CELL ADHESION INHIBITORS

CROSS-REFERENCE TO RELATED APPLICATIONS

This is a continuation-in-part of United States patent application Serial No. 08/376,372, filed 5 January 23, 1995, now pending.

TECHNICAL FIELD OF THE INVENTION

The present invention relates to novel compounds that are useful for inhibition and prevention of cell adhesion and cell adhesion-mediated pathologies. This invention also relates to pharmaceutical formulations comprising these compounds and methods of using them for inhibition and prevention of cell adhesion and cell adhesion-mediated pathologies. The compounds and pharmaceutical compositions of this invention can be used as therapeutic or prophylactic agents. They are particularly well-suited for treatment of many inflammatory and autoimmune diseases.

BACKGROUND OF THE INVENTION

Cell adhesion is a process by which cells associate with each other, migrate towards a specific target or localize within the extra-cellular matrix. As such, cell adhesion constitutes one of the fundamental mechanisms underlying numerous biological phenomena. For example, cell adhesion is responsible

for the adhesion of hemoatopoietic cells to endothelial cells and the subsequent migration of those hemopoietic cells out of blood vessels and to the site of injury. As such, cell adhesion plays a role in pathologies such 5 as inflammation and immune reactions in mammals.

Investigations into the molecular basis for cell adhesion have revealed that various cell-surface macromolecules -- collectively known as cell adhesion molecules or receptors -- mediate cell-cell and cell- 10 matrix interactions. For example, proteins of the superfamily called "integrins" are the key mediators in adhesive interactions between hematopoietic cells and their microenvironment (M.E. Hemler, "VLA Proteins in the Integrin Family: Structures, Functions, and Their 15 Role on Leukocytes.", Ann. Rev. Immunol., 8, p. 365 (1990)). Integrins are non-covalent heterodimeric complexes consisting of two subunits called α and β . There are at least 12 different α subunits ($\alpha 1-\alpha 6$, α -L, 20 α -M, α -X, α -IIB, α -V and α -E) and at least 9 different β ($\beta 1-\beta 9$) subunits. Based on the type of its α and β subunit components, each integrin molecule is categorized into a subfamily.

$\alpha 4\beta 1$ integrin, also known as very late antigen-4 ("VLA-4"), CD49d/CD29, is a leukocyte cell 25 surface receptor that participates in a wide variety of both cell-cell and cell-matrix adhesive interactions (M.E. Hemler, Ann. Rev. Immunol., 8, p. 365 (1990)). It serves as a receptor for the cytokine-inducible endothelial cell surface protein, vascular cell 30 adhesion molecule-1 ("VCAM-1"), as well as to the extracellular matrix protein fibronectin ("FN") (Ruegg et al., J. Cell Biol., 177, p. 179 (1991); Wayner et al., J. Cell Biol., 105, p. 1873 (1987); Kramer et al., J. Biol. Chem., 264, p. 4684 (1989); Gehlsen 35 et al. Science, 24, p. 1228 (1988)). Anti-VLA4

monoclonal antibodies ("mAb's") have been shown to inhibit VLA4-dependent adhesive interactions both in *vitro* and *in vivo* (Ferguson et al. Proc. Natl. Acad. Sci., 88, p. 8072 (1991); Ferguson et al., J. Immunol., 150, p. 1172 (1993)). Results of *in vivo* experiments suggest that this inhibition of VLA-4-dependent cell adhesion may prevent or inhibit several inflammatory and autoimmune pathologies (R. L. Lobb et al., "The Pathophysiologic Role of α -4 Integrins In Vivo", J. Clin. Invest., 94, pp. 1722-28 (1994)).

In order to identify the minimum active amino acid sequence necessary to bind VLA-4, Komoriya et al. ("The Minimal Essential Sequence for a Major Cell Type-Specific Adhesion Site (CS1) Within the Alternatively Spliced Type III Connecting Segment Domain of Fibronectin Is Leucine-Aspartic Acid-Valine", J. Biol. Chem., 266 (23), pp. 15075-79 (1991)) synthesized a variety of overlapping peptides based on the amino acid sequence of the CS-1 region (the VLA-4 binding domain) of a particular species of fibronectin. They identified an 8-amino acid peptide, Glu-Ile-Leu-Asp-Val-Pro-Ser-Thr [SEQ ID NO: 1], as well as two smaller overlapping pentapeptides, Glu-Ile-Leu-Asp-Val [SEQ ID NO: 2] and Leu-Asp-Val-Pro-Ser [SEQ ID NO: 3], that possessed inhibitory activity against FN-dependent cell adhesion. These results suggested the tripeptide Leu-Asp-Val as a minimum sequence for cell-adhesion activity. It was later shown that Leu-Asp-Val binds only to lymphocytes that express an activated form of VLA-4, thus bringing into question the utility of such a peptide *in vivo* (E.A. Wayner et al., "Activation-Dependent Recognition by Hematopoietic Cells of the LDV Sequence in the V Region of Fibronectin", J. Cell. Biol., 116(2), pp. 489-497 (1992)). However, certain larger peptides containing the LDV sequence were

subsequently shown to be active in vivo [T. A. Ferguson et al., "Two Integrin Binding Peptides Abrogate T-cell-Mediated Immune Responses In Vivo," Proc. Natl. Acad. Sci. USA, 88, pp. 8072-76 (1991); and S.M. Wahl et al., 5 "Synthetic Fibronectin Peptides Suppress Arthritis in Rats by Interrupting Leukocyte Adhesion and Recruitment," J. Clin. Invest., 94, pp. 655-62 (1994)].

A cyclic pentapeptide, Arg-Cys-Asp-TPro-Cys

10 (wherein TPro denotes 4-thioproline), which can inhibit both VLA-4 and VLA-5 adhesion to FN has also been described (D. M. Nowlin et al. "A Novel Cyclic Pentapeptide Inhibits $\alpha 4\beta 1$ and $\alpha 5\beta 1$ Integrin-mediated Cell Adhesion", J. Biol. Chem., 268(27), pp. 20352-59 15 (1993); and PCT publication PCT/US91/04862). This peptide was based on the tripeptide sequence Arg-Gly-Asp from FN which had been known as a common motif in the recognition site for several extracellular-matrix proteins.

20 Despite these advances, there remains a need for small, specific inhibitors of VLA-4-dependent cell adhesion. Ideally, such inhibitors would be semi-peptidic or non-peptidic so that they may be orally administered. Such compounds would provide useful 25 agents for treatment, prevention or suppression of various pathologies mediated by cell adhesion and VLA-4 binding.

SUMMARY OF THE INVENTION

The present invention solves this problem by 30 providing novel non-peptidic compounds that specifically inhibit the binding of ligands to VLA-4. These compounds are useful for inhibition, prevention and suppression of VLA-4-mediated cell adhesion and pathologies associated with that adhesion, such as 35 inflammation and immune reactions. The compounds of

this invention may be used alone or in combination with other therapeutic or prophylactic agents to inhibit, prevent or suppress cell adhesion. This invention also provides pharmaceutical formulations containing these

5 VLA-4-mediated cell adhesion inhibitors and methods of using the compounds and compositions of the invention for inhibition of cell adhesion.

According to one embodiment of this invention, these novel compounds, compositions and 10 methods are advantageously used to treat inflammatory and immune diseases. The present invention also provides methods for preparing the compounds of this invention and intermediates useful in those methods.

Compounds of this invention may be synthesized using any conventional technique.

20 Preferably, these compounds are chemically synthesized from readily available starting materials, such as α -amino acids. Modular and convergent methods for the synthesis of these compounds are also preferred. In a convergent approach, for example, large sections of the 25 final product are brought together in the last stages of the synthesis, rather than by incremental addition of small pieces to a growing molecular chain.

According to one embodiment, compounds of the present invention may be synthesized in the following 30 manner. A protected chiral amine is added to an α,β -

unsaturated ester to produce a protected β -amino acid ester. Upon suitable deprotection, the β -amino acid ester is coupled to an appropriate activated ester moiety. The coupled product, if suitably function-
5 alized, may be further reacted with yet another activated ester moiety. This material can be further manipulated to give the desired compounds of the invention. At each step of the above sequence, the ester can be hydrolyzed to the corresponding acid to
10 give another compound of the invention.

Alternatively, the activated ester moieties mentioned above can be attached together first, then the resulting compound can be attached to the β -amino acid ester portion. At this point the final
15 manipulations and/or necessary deprotection steps can be performed.

Alternatively, under suitable conditions, the desired functionalities can be incorporated (protected or unprotected) in one of the activated ester moieties.
20 That piece is then coupled with a β -amino acid ester or a moiety consisting of a β -amino ester previously coupled to an activated ester. The resulting product can then be subjected to any deprotection steps, if necessary, to give compounds of the invention.

25 Alternatively, the chiral β -amino acid esters used in the synthesis of the compounds of this invention may be synthesized by well-known techniques, such as those described in United States patent 5,344,957, the disclosure of which is herein
30 incorporated by references.

The compounds of this invention may also be modified by appending appropriate functionalities to enhance selective biological properties. Such modifications are known in the art and include those
35 which increase biological penetration into a given

biological system (e.g., blood, lymphatic system, central nervous system), increase oral availability, increase solubility to allow administration by injection, alter metabolism and alter rate of

5 excretion.

As used throughout this application, the term "patient" refers to mammals, including humans. And the term "cell" refers to mammalian cells, including human cells.

10 Once synthesized, the activities and VLA-4 specificities of the compounds according to this invention may be determined using in vitro and in vivo assays.

For example, the cell adhesion inhibitory 15 activity of these compounds may be measured by determining the concentration of inhibitor required to block the binding of VLA-4-expressing cells to fibronectin- or CS1-coated plates. In this assay microtiter wells are coated with either fibronectin 20 (containing the CS-1 sequence) or CS-1. If CS-1 is used, it must be conjugated to a carrier protein, such as bovine serum albumin, in order to bind to the wells. Once the wells are coated, varying concentrations of 25 the test compound are then added together with appropriately labelled, VLA-4-expressing cells.

Alternatively, the test compound may be added first and allowed to incubate with the coated wells prior to the addition of the cells. The cells are allowed to incubate in the wells for at least 30 minutes.

30 Following incubation, the wells are emptied and washed. Inhibition of binding is measured by quantitating the fluorescence or radioactivity bound to the plate for each of the various concentrations of test compound, as well as for controls containing no test compound.

VLA-4-expressing cells that may be utilized in this assay include Ramos cells, Jurkat cells, A375 melanoma cells, as well as human peripheral blood lymphocytes (PBLs). The cells used in this assay may 5 be fluorescently or radioactively labelled.

A direct binding assay may also be employed to quantitate the inhibitory activity of the compounds of this invention. In this assay, a VCAM-IgG fusion protein containing the first two immunoglobulin domains 10 of VCAM (D1D2) attached above the hinge region of an IgG1 molecule ("VCAM 2D-IgG"), is conjugated to a marker enzyme, such as alkaline phosphatase ("AP"). The synthesis of this VCAM-IgG fusion is described in PCT publication WO 90/13300, the disclosure of which is 15 herein incorporated by reference. The conjugation of that fusion to a marker enzyme is achieved by cross-linking methods well-known in the art.

The VCAM-IgG enzyme conjugate is then placed in the wells of a multi-well filtration plate, such as 20 that contained in the Millipore Multiscreen Assay System (Millipore Corp., Bedford, MA). Varying concentrations of the test inhibitory compound are then added to the wells followed by addition of VLA-4-expressing cells. The cells, compound and VCAM-IgG 25 enzyme conjugate are mixed together and allowed to incubate at room temperature.

Following incubation, the wells are vacuum drained, leaving behind the cells and any bound VCAM. Quantitation of bound VCAM is determined by adding an 30 appropriate colorimetric substrate for the enzyme conjugated to VCAM-IgG and determining the amount of reaction product. Decreased reaction product indicates increased cell adhesion inhibitory activity.

In order to assess the VLA-4 inhibitory 35 specificity of the compounds of this invention, assays

for other major groups of integrins, i.e., $\beta 2$ and $\beta 3$, as well as other $\beta 1$ integrins, such as VLA-5, VLA-6 and $\alpha 4\beta 7$ are performed. These assays may be similar to the adhesion inhibition and direct binding assays described above, substituting the appropriate integrin-expressing cell and corresponding ligand. For example, polymorphonuclear cells (PMNs) express $\beta 2$ integrins on their surface and bind to ICAM. $\beta 3$ integrins are involved in platelet aggregation and inhibition may be measured in a standard platelet aggregation assay. VLA-5 binds specifically to Arg-Gly-Asp sequences, while VLA-6 binds to laminin. $\alpha 4\beta 7$ is a recently discovered homologue of VLA-4, which also binds fibronectin and VCAM. Specificity with respect to $\alpha 4\beta 7$ is determined in a binding assay that utilizes the above-described VCAM-IgG-enzyme marker conjugate and a cell line that expresses $\alpha 4\beta 7$, but not VLA-4, such as RPMI-8866 cells.

Once VLA-4-specific inhibitors are identified, they may be further characterized in in vivo assays. One such assay tests the inhibition of contact hypersensitivity in an animal, such as described by P.L. Chisholm et al., "Monoclonal Antibodies to the Integrin $\alpha 4$ Subunit Inhibit the Murine Contact Hypersensitivity Response", Eur. J. Immunol., 23, pp. 682-688 (1993) and in "Current Protocols in Immunology", J. E. Coligan, et al., Eds., John Wiley & Sons, New York, 1, pp. 4.2.1-4.2.5 (1991), the disclosures of which is herein incorporated by reference. In this assay, the skin of the animal is sensitized by exposure to an irritant, such as dinitrofluorobenzene, followed by light physical irritation, such as scratching the skin lightly with a sharp edge. Following a recovery period, the animals are re-sensitized following the same procedure.

Several days after sensitization, one ear of the animal is exposed to the chemical irritant, while the other ear is treated with a non-irritant control solution. Shortly after treating the ears, the animals are given

5 various doses of the VLA-4 inhibitor by subcutaneous injection. In vivo inhibition of cell adhesion-associated inflammation is assessed by measuring the ear swelling response of the animal in the treated versus untreated ear. Swelling is measured using
10 calipers or other suitable instrument to measure ear thickness. In this manner, one may identify those inhibitors of this invention which are best suited for inhibiting inflammation.

Another in vivo assay that may be employed to
15 test the inhibitors of this invention is the sheep asthma assay. This assay is performed essentially as described in W. M. Abraham et al., "α-Integrins Mediate Antigeninduced Late Bronchial Responses and Prolonged Airway Hyperresponsiveness in Sheep," J. Clin. Invest.,
20 93, pp. 776-87 (1994), the disclosure of which is herein incorporated by reference. This assay measures inhibition of *Ascaris* antigen-induced late phase airway responses and airway hyperresponsiveness in asthmatic sheep.

According to this invention, the pharmaceutical compositions may be in the form of a sterile injectable preparation, for example a sterile injectable aqueous or oleaginous suspension. This

- 20 suspension may be formulated according to techniques known in the art using suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally-acceptable diluent or solvent, for example as a solution in 1,3-butanediol. solvent or suspending medium. For this purpose, any bland fixed oil may be employed including synthetic mono- or di-glycerides. Fatty acids, such as oleic acid and its glyceride derivatives are useful in the preparation of injectables, as do natural pharmaceutically-acceptable oils, such as olive oil or

castor oil, especially in their polyoxyethylated versions. These oil solutions or suspensions may also contain a long-chain alcohol diluent or dispersant, such as Ph. Hely or similar alcohol.

Carriers for topical administration of the compounds of this invention include, but are not limited to, mineral oil, liquid petrolatum, white petrolatum, propylene glycol, polyoxyethylene, polyoxypropylene compound, emulsifying wax and water. Alternatively, the pharmaceutical compositions can be formulated in a suitable lotion or cream containing the active components suspended or dissolved in one or more pharmaceutically acceptable carriers. Suitable carriers include, but are not limited to, mineral oil, sorbitan monostearate, polysorbate 60, cetyl esters wax, cetearyl alcohol, 2-octyldodecanol, benzyl alcohol and water.

5 The amount of active ingredient that may be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated, and the particular mode of administration. It should be understood, however, that a specific dosage and

10 treatment regimen for any particular patient will depend upon a variety of factors, including the activity of the specific compound employed, the age, body weight, general health, sex, diet, time of administration, rate of excretion, drug combination, and the judgment of the treating physician and the severity of the particular disease being treated. The amount of active ingredient may also depend upon the therapeutic or prophylactic agent, if any, with which the ingredient is co-administered.

15 The dosage and dose rate of the compounds of this invention effective to prevent, suppress or inhibit cell adhesion will depend on a variety of factors, such as the nature of the inhibitor, the size of the patient, the goal of the treatment, the nature of the pathology to be treated, the specific pharmaceutical composition used, and the judgment of the treating physician. Dosage levels of between about 0.001 and about 100 mg/kg body weight per day, preferably between about 0.1 and about 10 mg/kg body

20 weight per day of the active ingredient compound are useful.

Procedure A - Synthesis of Cinnamate Esters

Method A: To a cinnamic acid or substituted cinnamic acid (1.0 mmol) in CH_2Cl_2 (10 ml) was added $(\text{COCl})_2$ (1.5 mmol) slowly. The reaction mixture was stirred at r.t. for 4 h and the solvent was removed in vacuo to afford the acid chloride. Methanol or t-butyl alcohol (5 ml) was added to quantitatively provide the methyl or t-butyl ester after removal of the solvents.

15 Method B: To an appropriate aldehyde (1.0 mmol) in THF (10 ml) was added t-butoxycarbonyl methylene triphenylphosphorane (1.0 mmol, Aldrich) and the resulting mixture was stirred at room temperature for 16 h. The reaction mixture was diluted with petroleum ether (10 ml) and was filtered through a pad of celite. The filtrate was collected and concentrated in vacuo to afford the desired product.

Procedure B - Synthesis
of β -Amino Acids

15 A 2 L round bottom flask, equipped with a magnetic stir bar, was charged with 1000 mL of MeOH and the flask tared with its contents. Anhydrous HCl (11 g, 0.29 mol) was bubbled in from a cylinder. To this solution was added a cinnamic acid (0.29 mol) neat in
20 one portion. The resulting mixture was heated at reflux until the reaction was judged complete by TLC analysis. The reaction was cooled to RT, then refrigerated overnight. The crystalline product was collected by suction filtration on a medium frit and
25 the cake washed with cold MeOH. The solid was dried on the filter to give a white or nearly white product.

Michael addition of (R)-(+)-N-
10 benzyl-1-phenylethylamine to
methyl 4-methoxy-cinnamate

A 1 L 3-neck round bottom flask, equipped
with a stopper, thermometer, and 250 mL addition funnel
with an Ar inlet was charged with (R)-(+)-N-benzyl-1-
15 phenylethylamine hydrochloride (0.132 mol, 32.6 g, 1.1
eq based on cinnamate) and the apparatus flushed with
Ar 30 min. The salt was suspended in dry THF (200 mL)
and the mixture cooled to an internal temperature of -
70° C with a dry ice/acetone bath. To the suspension
was added n-BuLi (2.5 M in hexanes, 0.257 mol, 103 mL,
20 1.95 eq based on amine hydrochloride) from the addition
funnel at such a rate that the internal temperature did
not exceed -65° C. The addition required 90 min.
After completing the addition, the reaction was stirred
at -70° C for 1 hr. A solution of methyl 4-
25 methoxycinnamate (0.120 mol, 23 g, 1 eq) in THF (125
mL) was added from the addition funnel over 90 min at
such a rate that the internal temperature did not
exceed -65° C. After completing the addition, the
reaction was stirred at -70° C 2 hrs. TLC analysis
30 indicated complete reaction. The reaction was quenched
cold by the addition of 5% citric acid (250 mL) and
stirred overnight at RT. In a 2 L separatory funnel,
the layers were separated and the organic washed with
5% citric acid (1 x 125 mL). The combined aqueous were
35 extracted with EtOAc (1 x 200 mL). The combined

organics were then washed with 5% NaHCO₃ (1 x 150 mL) and brine (1 x 150 mL) and dried (MgSO₄). Filtration and evaporation to constant weight provided crude product (50.04 g, 103% of theory) as a viscous oil

5 which solidified on standing. Pure material was obtained by triturating and stirring crude product with heptane (1.5-2 mL/g, 75-100 mL total volume) at RT overnight. The solids were collected by suction filtration on a medium frit and the cake washed by 10 flooding with cold heptane (2 x 50 mL). The solids were dried on the filter to give pure product (28.93 g, 60% yield) as a white powder. TLC (4:1 hexane/EtOAc): R_f = 0.50 (I₂, UV); mp = 87-88° C; ¹H NMR (CDCl₃, 300 MHz): 1.20 (d, 3H, J = 6.9 Hz), 2.51 (dd, 1H, J = 9.4, 14.8 Hz), 2.66 (dd, 1H, J = 5.7, 14.8 Hz), 3.45 (s, 3H), 3.67 (ABq, 2H, J = 14.7 Hz), 3.79 (s, 3H), 3.98 (q, 1H, J = 6.8 Hz), 4.37 (dd, 1H, J = 5.7, 9.3 Hz), 6.86 (d, 2H, J = 8.6 Hz), 7.16-7.33 (m, 10 H), 7.40 (d, 2H, J = 7.3 Hz); MS (FAB): 404

20 Hydrogenolysis of
benzyl groups

The above adduct (0.071 mol, 28 g) was suspended in MeOH (300 mL) and treated with formic acid (96%, 0.179 mol, 8.25 g, 6.8 mL, 2.5 eq) neat in one portion with stirring. To this suspension was added Degussa type E101 NE/W 10% Pd/C (50% wet, 0.00179 mol, 3.81 g, 0.025 eq) in one portion. The resulting mixture was heated at reflux for 1-2 hr until judged complete by TLC analysis. The mixture was cooled to 30 RT, then filtered on a pad of Celite, washing the flask and pad with MeOH (150 mL). The combined filtrates were evaporated to give crude product (15.42 g, 102% of theory) as an oil. The crude product was dissolved in i-PrOH (250 mL) and heated to a gentle reflux. D-

tartaric acid (0.071 mol, 10.76 g, 1 eq) was added as a solid in one portion. Heating was continued for 15 min, during which time the salt precipitated as a fine white solid. The mixture was cooled to RT, then

5 refrigerated overnight. The crystalline salt was collected by suction filtration on a medium frit, washing with cold i-PrOH (50-75 mL), and dried on the filter to give product (23 g, 79%). The above salt was converted to the free base by dissolving in a minimum 10 volume of H₂O (125 mL) and treating the solution with solid NaHCO₃, until the aqueous was saturated. This was extracted with EtOAc (3 x 100 mL). The combined organics were washed with brine (1 x 100 mL) and dried (MgSO₄). Filtration and evaporation provided pure 15 product (11.75 g, 78%) as a nearly colorless oil which solidified on cooling.

To prepare **8-13** amino acid

1M TMSCl in CH_2Cl_2 (33 ml, 33 mmol) was added to a mixture of (R)- α -methylbenzylamine (3.4 g, 28 mmol) and Et_3N (4 g, 40 mmol) in THF (10 ml) was added and the mixture was allowed to stir for 1 h at room temperature. After the solid was removed by filtration, the solution was concentrated to afford a liquid. This silylamine (2.4 g, 12.5 mmol) was dissolved in THF (35 ml) and was cooled to -78°C . To this cooled solution was added n-BuLi (7.8 ml of 1.6 M solution in hexanes, 12.5 mmol) slowly. After stirring for 0.5 h at the temperature, to the reaction mixture was added a solution of t-butyl *trans*-3-(3-pyridyl)acrylate (2.56 g, 12.4 mmol) in THF (10 ml). The stirring was continued for another 1/2 h and the mixture was quenched with sat. NH_4Cl (20 ml) and was allowed to warm up to room temperature and extracted with ether. The combined ether layers were dried (K_2CO_3) and concentrated to afford an oil. This oil (500 mg) was dissolved in ethanol (1.5 ml), t-butanol (15 ml), ammonium formate (1.5 g) and 10% Pd/C (1.2 g) were added. The resulting mixture was heated to reflux for 3 h followed by acid and base workup to afford the desired amine β -13 (300 mg). FAB-MS = 223.

After stirring for 3h at room temperature, the reaction was diluted with water (20 mL) and washed twice with ethyl acetate (10 mL). The aqueous was then acidified to PH = 1-2 with 1N HCl and the aqueous layer extracted five times with ethyl

acetate, dried over Na_2SO_4 and concentrated to afford 1106-1 (842 mg, 51%). ^1H NMR (CDCl_3 , 300 MHz, ppm): 4.61 (1H, bs), 3.15-2.95 (4H, bm), 2.55-2.23 (4 H, m), 1.65-1.50 (4 H), 1.46 (9 H), 1.45-1.30 (2 H, m).

10 EXAMPLE 67
Inhibition of VLA4-Dependent Adhesion to BSA-CS1

This assay was used to assess the potency of VLA4-directed inhibitory compounds of this invention.

15 1. Conjugation of CS1 to BSA

We dissolved BSA-SMCC (Pierce Chemical, Rockford, IL; Catalog # 77115) in H₂O at a concentration of 10 mg/mL. [SEQ ID NO:4] :Cys-Tyr-Asp-Glu-Leu-Pro-Gln-Leu-Val-Thr-Leu-Pro-His-Pro-Asn-Leu-His-Gly-Pro-Glu-Ile-Leu-Asp-Val-Pro-Ser-Thr ("Cys-Tyr-CS1 peptide"), which 20 we synthesized by conventional solid phase chemistry and purified by HPLC, was dissolved in 10mM HEPES pH 5, 50 mM NaCl and 0.1 mM EDTA also at a concentration of 10 mg/mL. We then mixed 500 μ L of BSA-SMCC, 250 μ L of Cys-Tyr-CS1 peptide and 75 μ L of 1 mM HEPES pH 7.5 and 25 allowed the conjugation reaction to proceed for 30 minutes. We stopped the reaction by adding 1 μ L of beta-mercaptoethanol. Samples were analyzed for cross-linking by SDS-PAGE. This reaction produced multiple molecules of the Cys-Tyr-CS1 peptide conjugate to each 30 BSA molecule.

2. Preparation of Plates for Adhesion Assay

We coated the wells of a Linbro titertek polystyrene 96-well flat bottom plate (Flow Laboratories, Maclean, VA; catalog #76-231-05) with 100 μ L of the above-described BSA-CS1 solution diluted to 1 5 μ g/mL in 0.05 M NaHCO₃ (15mM NaHCO₃, 35mM Na₂CO₃) pH 9.2. Some wells were not coated with CS1 in order to assess non-specific cell binding (NSB). The plate was then incubated overnight at 4°C.

Following this incubation, the contents of the 10 wells were removed by inverting and blotting the plate. All of the wells were then blocked with 100 μ L of 1% BSA in PBS, 0.02% NaN₃, for a minimum of one hour at room temperature.

15 3. Preparation of Fluorescently Labelled Ramos Cells

Ramos cells are grown, maintained and labelled in RPMI 1640 culture medium containing 1% BSA. Just prior to running the assay, we added 2',7'-bis-(2-carboxyethyl)-5 (and -6) carboxyfluorescein 20 acetoxymethyl ester ("BCECF-AM"; Molecular Probes Inc., Eugene, Oregon; catalog #B-1150) to a final concentration of 2 μ M to a culture of Ramos cells (4×10^6 cells/mL). We incubated the cells for 20 minutes at 37°C.

25 Following labelling, the cells were washed twice in assay buffer (24 mM TRIS, 137 mM NaCl, 2.7 mM KCl, pH 7.4, containing 0.1% BSA and 2mM glucose) to remove any cations originating from the culture medium. The cells were then resuspended in assay buffer to 4×10^6 cells/mL 30 and 2mM MnCl₂ was added to upregulate VLA4 on the surface of the cells.

4. Running the Assay

Immediately prior to running the assay, we removed the BSA blocking solution from the 96-well

plates and washed the wells with 100 μ L of assay buffer. We then added to each well 25 μ L of test compound at 2x the final concentration and 25 μ L of the labelled Ramos cells. Final concentrations were selected across a 5 range of anticipated IC50s, usually between 0.01 nM - 10 μ M. Each concentration of compound was tested in triplicate. The compound and cells are allowed to incubate for 30 minutes at room temperature.

10 We then emptied the contents of the plate and washed the wells 4 times with assay buffer. Using a light microscope, we examined the the NSB wells. If more than a few cells are bound to those wells, we washed the plate once more to remove the excess non-specifically bound cells.

15 Binding of the Ramos cells to the CS1 peptide-coated wells was measured by adding 100 μ L of assay buffer to each well and quantitating fluorescence in a Millipore Cytofluor 2300 System platereader set at 485 nm excitation and 530 nm emission. Binding was 20 expressed as an IC50 -- the concentration of inhibitor at which 50% of control binding occurs. Percent binding is calculated by the formula:

25
$$[(F_{TB} - F_{NS}) - (F_I - F_{NS})] / [(F_{TB} - F_{NS})] \times 100 = \% \text{ binding}$$
, where F_{TB} is total fluorescence bound to CS1-containing wells without added inhibitor; F_{NS} is fluorescence bound in wells lacking CS1; and F_I is fluorescence bound in wells containing an inhibitor of this invention.

30 Other compounds according to this invention were similarly assayed. The IC50 for each of these compounds is indicated in the table below:

EXAMPLE 68

Direct Binding Of VLA4-Presenting Cells To VCAM-IgG

We next examined the ability of the compounds of this invention to inhibit VCAM/VLA4 binding, utilizing a 5 VCAM-IgG-alkaline phosphatase conjugate. To carry out this assay, we used the Millipore Multiscreen Assay System (Millipore Corp., Bedford, MA) to wash the cells efficiently.

1. Preparation of VCAM-IgG-AP conjugates

10 The construction of VCAM 2D-IgG expression vectors, transfection of CHO cells with those constructs and purification of the resulting expression product is described in PCT publication WO 90/13300, the disclosure of which is herein incorporated by reference.

15 1.2 ml of purified VCAM 2D-IgG (5 mg/ml in 10 mM HEPES, pH 7.5) was reacted with 44 μ l of Traut's reagent (2-iminothiolane, 20 mg/ml in water; Pierce Chemical, Rockford, IL.) at room temperature for 30 minutes. The sample was desalted on a 15 ml Sephadex G-25 column 20 equilibrated with 100 mM NaCl, 10 mM MES, pH 5.0. One ml fractions were collected and absorbance at 280 nm was determined. The two peak fractions were pooled.

One ml of calf intestinal alkaline phosphatase (19 mg/ml; Pierce Chemical, Rockford, IL) was reacted 25 with 100 μ l of sulfo-SMCC (30 mg/ml in water) and 100 μ l 1 M HEPES, pH 7.5 for 35 minutes at room temperature. The reaction mix was desalted on a 12 ml Sephadex G-25 column equilibrated with 150 mM NaCl, 10 mM HEPES, pH 6.0. One ml fractions were collected and absorbance at 30 280 nm was determined. The two peak fractions were pooled and stored on ice.

The alkaline phosphatase-SMCC and VCAM 2D-IgG-iminothiolane adducts were cross-linked at a molar ratio of 2:1 in Tris-HCL, pH 7.5 by incubation at room

temperature for 30 minutes. Extent of cross-linking was determined by SDS-PAGE. The cross-linked products were stabilized by the addition of 2 mM MgCl₂ and 0.25 nM ZnCl₂ and stored at 4°C.

5 2. Binding Assay

We first blocked a 96-well filtration plate for by adding 275 µL of PBS containing 0.1% Tween 20 and 2% BSA ("blocking buffer") to each well and incubating for 1 hour at room temperature. The plate was then placed 10 onto a vacuum manifold and the blocking buffer was drained through the bottom of the filtration wells into a waste collection tray. Then we washed the wells three times with 200-250 µL of Tris-buffered saline, containing 0.1% BSA, 2 mM glucose and 1 mM HEPES, pH 7.5 15 ("assay buffer") to wash out any remaining blocking buffer. We then drained the plates and blotted them on paper towels to remove buffer on the underside of the plate.

We then prepared a stock solution of VCAM-IgG-AP 20 (4 µg/mL in assay buffer) and filtered it through a 0.2 µ low protein binding syringe filter (Gelman Sciences, Ann Arbor, MI # 4454). This solution was then diluted 1:10 in assay buffer and 25 µL was added to every well of the washed plate.

25 We diluted the cell adhesion inhibitor being tested to 2x final concentration in assay buffer and added 25 µL of each dilution to triplicate wells in the plate. Final concentrations used ranged from 0.01 nM - 10 µM. Control wells for total binding and non-specific 30 binding received 25 µL of assay buffer, instead of inhibitor. Total binding wells contained cells and VCAM-IgG-AP in assay buffer. Non-specific binding wells contained only VCAM-IgG-AP in assay buffer.

Jurkat cells were washed once in assay buffer to 35 remove growth medium and resuspended at 8 x 10⁶/mL in

assay buffer containing 2 mM MnCl₂. We added 50 μ l of Jurkat cells to every well, except the non-specific binding wells, which received 50 μ L of assay buffer to maintain a final assay volume of 100 μ L per well. We 5 gently mixed the contents of the wells by tapping the sides of the plate. The plate was then allowed to incubate undisturbed for 60 minutes at room temperature.

At the end of the 60 minute incubation, we placed the plate on the vacuum manifold to drain the 10 wells. We carefully added 100 μ L of assay buffer containing 1mM MnCl₂ (wash buffer) to each well so as not to disturb the cells on the bottom. The wash buffer was removed by vacuum and the plate was washed again with 150 μ L of wash buffer. After draining the wash buffer 15 again, the underside of the plate was blotted on paper towels.

Next, we prepared a 10 mg/mL solution of 4-nitrophenylphosphate in 0.1 M glycine, 1 mM ZnCl₂, pH 10.5 (substrate buffer) and added 100 μ L immediately 20 added to each well. The plate was incubated for 30 minutes at room temperature to allow the colorimetric reaction to proceed. We stopped the reaction by adding 100 μ L of 3 N NaOH to each well.

The contents of the 96-well filtration plate was 25 then transferred directly into a 96-well flat bottom plate using the vacuum manifold. The plate was read at a wavelength of 405 nm to determine the amount of VCAM conjugate bound to the cells. Percent binding is calculated by the formula:

30 $[(A_{TB} - A_{NS}) - (A_I - A_{NS})] / [(A_{TB} - A_{NS}) \times 100] = \% \text{ binding}$, where A_{TB} is the absorbance at 405 nm of CS1-containing wells without added inhibitor; A_{NS} is the absorbance at 405 nm in wells lacking CS1; and A_I is absorbance at 405 nm in wells containing an inhibitor of this invention

invention in the same assay. The IC50 values are comparable to those derived from the CS1 binding assay described in the previous example, although certain compounds demonstrated up to 10-fold greater binding in 5 this assay than in the previous assay.

EXAMPLE 69

Inhibition Of Mouse Contact Hypersensitivity

We anesthetized 20-g female Balb/c mice (Jackson Laboratories, Bar Harbor, ME) with sodium pentobarbital 10 (90 mg/kg, i.p.). A 3 cm² patch of abdominal skin was then exposed by closely shaving the fur. The skin was then scrubbed with 70% ethanol, followed by application of 25 μ L of 0.5% DNFB in 4:1 v/v acetone:olive oil onto the bare abdominal skin. We then lightly scratched the 15 skin with the applying pipet tip to encourage mild inflammation. Twenty four hours after the initial sensitization we again sensitized the mouse with 25 μ L of 0.5% DNFB at same abdominal skin location, again followed by light scratching with the pipet tip. The 20 second sensitization was performed while restraining the unanesthetized mouse.

On Day 5 (120 hours after the initial sensitization), we anesthetized the mice with 90:10 mg/kg ketamine:xylazine, i.p. and applied a sub-irritant 25 dose of 10 μ L of 0.2% DNFB to the dorsal surface of the left ear. The right ear received a similar application of the 4:1 v/v acetone:olive oil vehicle.

Four hours after challenging the immune response, we administered various concentrations of the 30 inhibitors of this invention to the mice in 100 μ L 0.5% sodium phosphate buffer, pH 8.8, and 3% v/v DMSO by subcutaneous (s.c.) injection. Less soluble inhibitors occasionally required up to 30% DMSO addition the highest concentrations tested. Groups of 8 mice were

used for each treatment tested. Positive (PS2 anti-mouse VLA-4 antibody, 8 mg/kg, i.v.), and negative control (phosphate-buffered physiological saline; PBS, 100 μ L i.v.; DMSO in PBS, 100 μ L s.c.) groups were 5 routinely tested for comparison as part of the assay of test compounds.

Twenty four hours after challenge mice were again anesthetized with ketamine:xylazine and the ear thickness of both ears measured with an engineer's 10 micrometer to an accuracy of 10^{-4} inches. The ear swelling response for each mouse was the difference between its control- and DNFB-challenged ear thickness. Typical uninhibited ear swelling responses were $65-75 \times 10^{-4}$ in. Inhibition of the ear swelling response was 15 judged by comparison of treated groups with their negative control group. Percent inhibition was calculated as:

$$20 \quad \frac{[(\text{mean negative control group ear swelling}) - (\text{mean test group ear swelling})]}{\text{mean negative control group ear swelling}} \cdot 100$$

Statistical significance of the difference among treatment groups was evaluated using one-way analysis of variance followed by computation of the Tukey-Kramer 25 Honestly Significant Difference (JMP, SAS Institute) using $p<0.05$.

The inhibitors of this invention cause a statistically significant reduction in the ear swelling response of DNFB-treated mice as compared to uninhibited 30 control animals.

EXAMPLE 70

Inhibition Of *Ascaris* Antigen-Induced Late Phase Airway Sensitivity In Allergic Sheep

Sheep which had previously been shown to develop 35 both early and late bronchial responses to *Ascaris suum*

antigen were used in this study. The protocol used for the experiment was that described in W. M. Abraham et al., J. Clin. Invest., 93, pp. 776-87 (1994), except that the VLA-4 inhibitors of this invention were 5 administered to the animals was dissolved in 3-4 ml of 50% aqueous ethanol and delivered by aerosol spray.

The results showed that all of the VLA-4 inhibitors of this invention inhibited the airway responses associated with administration of *Ascaris suum* 10 antigen.

While we have hereinbefore presented a number of embodiments of this invention, it is apparent that our basic construction can be altered to provide other compounds and methods which utilize the compounds of 15 this invention. Therefore, it will be appreciated that the scope of this invention is to be defined by the claims appended hereto rather than the specific embodiments which have been presented hereinbefore by way of example.
